NO. OF SHEETS 4 ^{2 of 4} SHEET 2

WHERE USED 077 - Collator

DATE

7. Collation of a predetermined number of primary and secondary cards.
8. Insertion of a variable number of secondary cards from 1 to 9, behind a single primary card, the number being automatically determined as the difference between the digit punched in the primary card and a predetermined number plugged on the board.
9. Consecutive Number Checking.

For plugging charts and a more detailed description of the various operations, it is suggested that reference be made to *Principles of Operation, Collator Type 077, Form 52-3185*.

The functions of the various circuits are as follows:

The counting circuits are plugged from PS, P C AND S hubs to the units "IN" and tens "IN". Therefore, the counting relays always pickup at 201°. The holding circuit for these relays is held until 0° thru CR-11. At 270° CR-9 makes and completes the circuit to the step relay coil through relays 42-B and 41-B.

Relays R-43 and 44 are the 9's test relays. Relay R-39 and 40 are the restoring relays for the step units. Relays R-41 and 42 are the carry control and automatic restoration when the step relays reach 9. Relay R-47 is in parallel with the respective card lever relay to provide the necessary capacity for card lever control of the source hubs. The purpose of 19 BU and 19 BL is to insure the step relays being at zero at the beginning of a run.

The "Units Break" and "Tens Break" contacts mounted on the respective relays serve as drop-out points when the relays are restored to their zero position.

Assume a straight counting operation when the total number is greater than 10. Counting to be controlled from the primary brush station #2.

A plugwire will be placed from "P" hub to "U" "IN" hub. The carry switch is plugged on and the "U-C" hub is plugged to tens hub corresponding to the tens digit being counter.

"Control Inputs"
By plugging from ~~171/172/173/174~~ of the standard section to the units hub corresponding to the digit being counted, and from the "T-C" hub to the "PU" of a standard selector, this selector can be used to control feeding of the two units under control of the counter.

At 201° on each primary cycle as the cards pass the primary brushes #2 relay 45 will be energized. A holding circuit is established through CR 11 until 0°. At 270° CR-9 completes a circuit through Rel. 45 B and 42 B to the units count magnet. This circuit causes the units step relay to advance one position for each primary cycle. After having counted 9 cards, the circuit for carry is as follows:

At 221° on the 10th count cycle CR 10 completes the circuit through R-43 and 44. Through the transferred points of R-43 A & B and R-44 A & B a test is made from CR-10 through the 9 spots on the units and tens step relays.

Assuming the units step relay has reached 9, a circuit is completed through R-43 A, 9 spot R-43 B and relay 42 and holding through CR-11.

At 270° on the same cycle (Primary) CR-9 completes a circuit through R-45 B, R-42B, carry switch, normally closed 41 (B) to tens count magnet. A parallel circuit is also completed through 45 B, 42 AL to units restoring magnet. Thus, on the 10th cycle, a one is counted into the tens step relay and the units step relay is restored to zero.

If it happens that both the units and tens step relays were holding 9's it can be seen that the 100th impulse will pass through R-45 B, 42 (B) energized, 41 B energized, and tens restoring magnet as well as through the 42 AL points and units restoring magnet.

When it is desired to restore the step relays from some source outside the counter circuit, relays R-39 and 40 must be plugged to the source and it may be any of the normal machine sources.

When insertion is to be controlled by the selector unit it is necessary to plug 0-9 inputs of the units and tens step relays together by means of bottle plugs, and then plug the transfer switch "ON".

A number may then be read from the card into one side of the selector unit in the normal manner. The output of the step relays is then plugged to the other side of the selector unit. Counting and carrying are in the normal manner.

During the reading portion of each machine cycle the figures in the step relays are read into the selector units, under control of the emitter. This reading compares in the normal manner with the figures read directly from the card. The selector output is used to control feeding.
